# ON THE TOTAL CURVATURE OF MINIMIZING GEODESICS ON CONVEX SURFACES

### NINA LEBEDEVA AND ANTON PETRUNIN

ABSTRACT. We give a universal upper bound for the total curvature of minimizing geodesic on a convex surface in the Euclidean space.

### 1. Introduction

Denote by  $\mathbb{E}^3$  the 3-dimensional Euclidean space.

Recall that the total curvature of a curve  $\gamma \colon [0,\ell] \to \mathbb{E}^3$  (briefly TotCur $\gamma$ ) is defined as supremum of sum of exterior angles for the broken lines inscribed in  $\gamma$ . If  $\gamma$  is smooth and equipped with the natural parameter, then

$$\operatorname{TotCur} \gamma = \int_{0}^{\ell} \kappa(t) \cdot dt,$$

where  $\kappa(t) = |\gamma''(t)|$  is the curvature of  $\gamma$  at t.

**1.1. Main theorem.** If K is a closed convex set in the 3-dimensional Euclidean space,  $\Sigma$  is the surface of K and  $\gamma$  be a minimizing geodesic in  $\Sigma$  then

$$\operatorname{TotCur} \gamma \leq \omega$$
,

where  $\omega$  is a universal real constant.

The question was stated in [1], [2] and [3], but we have learned it from Dmitry Burago only few years ago.

Let us briefly discuss the related results.

- $\diamond$  In [4], Liberman gives a bound on the turn of short geodesic in terms of the ratio diameter and inradius of K. In the proof he use now so called Liberman's lemma 2.1 discussed below. This statement was rediscovered in [3].
- $\diamond$  In [5], Usov gives the optimal bound for total curvature of geodesic on the graph of  $\ell$ -Lipscitz convex function. Namely, he proves that if  $f: \mathbb{R}^2 \to \mathbb{R}$  is  $\ell$ -Lipschitz and convex then any geodesic in its graph

$$\Gamma_f = \left\{ (x, y, z) \in \mathbb{R}^3 \mid z = f(x, y) \right\}$$

has turn at most  $2 \cdot \ell$ . This statement was also rediscovered in [3]. Yet an amusing generalization of Usov's result is given by Berg in [6].

In [7], Pogorelov conjectured that any the spherical image of geodesic on convex surface has to be contructable. It is easy to see that the length of spherical image of geodesic can not be smaller than its total curvature, so this conjecture (if it would be true) would be stronger than Liberman's theorem. Counterexamples were found indepenently by Milka in [8], Usov in [9] and much later by Pach in [2].

A. Petrunin was partially supported by NSF grant DMS 1309340.

- In [3], Bárány, Kuperberg, and Zamfirescu have constructed a corkscrew minimizing geodesic on a closed hypersurface; that is a minimizing geodesic which twists around given line arbitrary many times.
- $\diamond$  In the same paper they also constructed a minimizing geodesic on a convex surface in  $\mathbb{R}^3$  with total curvature bigger that  $2 \cdot \pi$ . (Note that  $2 \cdot \pi$  is the optimal bound for the analogous problem in the plane.)

# **Plan of the proof.** We prove is divided in three steps.

First we prove a sequence of propositions which alow us to consider only special case of surfaces and curves. Namely we show that we can assume that

- (i) (Proposition 3.1). The surface  $\Sigma$  is  $C^{\infty}$ -smooth.
- (ii) (Proposition 5.1). The z-component of  $\gamma'$  is positive,
- (iii) (Proposition 6.3). The surface  $\Sigma$  is formed by a graph z = f(x, y) of a smooth convex function  $f: \mathbb{R}^2 \to \mathbb{R}$ .

On the second step we give number of geometric inequalities which relate the angles between  $\gamma'(t)$  and with the coordinate axis.

The last step in the proof is purely algebraic, here we combine the obtained inequalities to give a universal bound on the total curvature of  $\gamma_n$  which satisfies the conditions (i)–(i).

# 2. Preliminaries

Let  $\Sigma$  be a convex hypersurface in the Euclidean space.

Given a point  $p \in \Sigma$ , we will denote by  $n_p$  the outer normal vector of  $\Sigma$  at p; the map  $\Sigma \to \mathbb{S}^2$  defined as  $p \mapsto n_p$  sometimes is called Gauss map.

Fix a points  $z \notin \Sigma$ . Given a point  $p \in \Sigma$ , we say that p lies on light (dark) side from z if if  $\langle z - p, n_p \rangle \leq 0$  (correspondingly  $\langle z - p, n_p \rangle \geq 0$ ). If  $\langle z - p, n_p \rangle = 0$  we say that p lies on the horizon from p. Note that if z lies inside of  $\Sigma$  then all points on  $\Sigma$  lie on the dark side from z.

Let  $\gamma$  be a space curve parametrized by length. Fix a point  $z \notin \gamma$ . Let us define Liberman's development of  $\gamma$  with respect to z as the unit-speed plane cure  $\tilde{\gamma}_z$  such that the direction  $\tilde{\gamma}_z(t)$  changes counterclockwise as t changes and  $|\tilde{\gamma}_p(t)| = |\gamma(t) - z|$  for any t.

The Liberman's development  $\tilde{\gamma}_z$  is called convex concave at  $\tilde{\gamma}_z(t)$  if there the curvelinear triangle ???

**2.1. Liberman lemma.** Let  $\Sigma$  be a convex surface in the Euclidean space  $z \notin \Sigma$  and  $\gamma$  be a unit-speed geodesic in  $\Sigma$ . Then the development  $\tilde{\gamma}_z$  is locally convex (concave) at the points on dark (light) side of  $\Sigma$  with respect to z.

Assume  $\gamma \colon [0,\ell] \to \Sigma$  is a unit-speed curve in the space.

The vector  $\gamma''(t)$  is the curvature vector of  $\gamma$  at t. The total curvature of  $\gamma$  can be defined as

$$\operatorname{TotCur} \gamma \stackrel{\operatorname{def}}{=} \int_{0}^{\ell} |\gamma''(t)| \cdot dt.$$

The total curvature of  $\tilde{\gamma}_z$  is called the total curvature of  $\gamma$  in the direction of z and denoted as  $\operatorname{TotCur}_z \gamma$  Given a point z, let us define the total curvature of  $\gamma$  in the direction of z as

$$\operatorname{TotCur}_{z} \gamma \stackrel{\operatorname{def}}{=} \int_{0}^{\ell} \left| \langle \gamma''(t), \frac{z - \gamma(t)}{|z - \gamma(t)|} \rangle \right| \cdot dt.$$

**2.2. Key Lemma.** Let  $\gamma \colon [0,\ell] \to \Sigma$  be a geodesic on the convex surface in the Euclidean space and  $u \in \mathbb{S}^2$ . Assume that  $0 = t_0 < t_1 < \cdots < t_n = \ell$  be the values

such that each arcs  $\gamma|_{[t_{i-1},t_i]}$  alternating light and dark side of  $\Sigma$  with respect to u. Set  $\alpha_i = \measuredangle(\gamma'(t_i),u)$  Then

$$\operatorname{TotCur}_{u} \gamma = |\sum_{i} (-1)^{i} \alpha_{i}|.$$

Moreover, if 1 < i < n and  $\Omega_i$  denotes the domain of  $\Sigma$  bounded by the arc  $\gamma|_{[t_{i-1},t_i]}$  and the u-horizon then

$$|\alpha_i - \alpha_{i-1}| \leq \operatorname{curv} \Omega_i$$

where curv  $\Omega_i$  denotes the total curvature of  $\Omega_i$ . In particular,

$$\operatorname{TotCur}_{u} \gamma \leqslant 4 \cdot \pi + \sum_{i} \operatorname{curv} \Omega_{i}.$$

**Remarks.** Clearly  $\operatorname{TotCur}_z \gamma \leq \operatorname{TotCur} \gamma$  for any curve  $\gamma$  in  $\Sigma$ .

On the other hand given few points  $z_i$  which do not lie in one plane one can estimate TotCur $\gamma$  in terms of TotCur $z_i$  $\gamma$  the distances between  $z_i$  and the maximal distance to  $\gamma$ .

Let  $N=N(\Sigma,\gamma,u)$  be the maximal integer such that at most N of the domains  $\Omega_i$  intersect at one point. Note that from [3], it follows that the value N can take arbitrary large value. The number N can be estimated through the maximal rotation number of subarcs of  $\gamma$  with respect to the lines. In particular the total curvature of geodesic  $\gamma$  can be bounded in terms of maximal rotation number of subarcs of  $\gamma$  around the lines. The later was claimed in [3] without a proof.

Then

$$\sum_{i=2}^{n-1} \operatorname{curv} \Omega_i \leqslant N \cdot \operatorname{curv} \Sigma \leqslant 4 \cdot N \cdot \pi.$$

Therefore, we get an estimate

$$\operatorname{TotCur}_{u} \gamma \leqslant 4 \cdot N \cdot \pi + |\alpha_{0} - \alpha_{1}| + |\alpha_{n-1} - \alpha_{n}| \leqslant (4 \cdot N + 2) \cdot \pi.$$

Since the same holds for any vector u, we can taking avarage we get

$$\operatorname{TotCur} \gamma \leq 3 \cdot (4 \cdot N + 2) \cdot \pi.$$

# 3. Smoothing

**3.1. Proposition.** Let  $K_1, K_2, \ldots, K_{\infty}$  be closed convex sets in  $\mathbb{R}^3$  and  $K_n \to K_{\infty}$  in the sense of Hausdorff. Then for any minimizing geodesic  $\gamma_{\infty}$  in the surface of  $K_{\infty}$  there is a sequence of minimizing geodesics  $\gamma_n$  in the surface of  $K_n$  such that  $\gamma_n \to \gamma_{\infty}$ .

*Proof.* Assume  $\gamma$  is a minimizing geodesic on a convex surface  $\Sigma$ . Assume  $\gamma$  parametrized by its length  $[0,\ell]$ . We can choose a subinterval  $[a,b] \subset [0,\ell]$  such that 0 < a and  $b < \ell$  and  $\text{TotCur}(\gamma|_{[a,b]})$  is arbitrary close to the  $\text{TotCur}\,\gamma$ .

Set 
$$p = \gamma(a)$$
 and  $q = \gamma(b)$ .

Assume  $\Sigma_n$  be a sequence of smooth convex surfaces converging to  $\Sigma$ . and  $p_n, q_n \in \Sigma_n$  be a two sequences of points which converge to p and q correspondingly.

Denote by  $\gamma_n$  a minimizing geodesic from  $p_n$  to  $q_n$  in  $\Sigma_n$ . Note that  $\gamma_n$  converges to  $\gamma|_{[a,b]}$  as  $n \to \infty$ .

#### 4

### 4. Length and diameter

Let  $\varepsilon > 0$ . A curve  $\gamma \colon [a,b] \to \mathbb{R}^3$  will be called  $\varepsilon$ -straight if

length 
$$\gamma \leqslant e^{\varepsilon} \cdot |\gamma(b) - \gamma(a)|$$

**4.1. Lemma.** Given  $\varepsilon > 0$  there is  $\delta > 0$  (any  $\delta < (1 - e^{-\varepsilon})/2$  will do) such that in any minimizing geodesic of length  $\ell$  on a convex surface  $\Sigma$  in  $\mathbb{R}^3$  there an  $\varepsilon$ -straight arc of length at least  $\delta \cdot \ell$ ;

*Proof.* Set  $\alpha = \arccos e^{-\varepsilon}$ . Let N be the maximal number of points in  $\mathbb{S}^2$  which lie on distance at least  $2 \cdot \alpha$  from each other.

Let  $\gamma \colon [0,\ell] \to \Sigma$  be a minimizing geodesic parametrized by its length.

Given a value  $t \in [0, \ell]$ , set t' to be the maximal value in  $[0, \ell]$  such that the interval [t, t'] i  $\varepsilon$ -straight.

Consider the maximal sequence  $0 = t_0 < t_1 < \dots < t_n < \ell$  such that  $t_{i+1} = t'_i$ .

Denote by  $\nu_i$  the outer unit normal vector to  $\Sigma$  at  $\gamma(t_i)$ . Note that  $\angle(\nu_i, \nu_j) > 2 \cdot \alpha$  for all i and j. It follows that the sequence  $(t_i)$  terminates after at most N steps. Therefore any  $\delta < \frac{1}{N+1}$  does the job.

**4.2. Lemma.** Assume  $\gamma$  is a minimizing geodesic on a convex surface in  $\mathbb{R}^3$ . Then

length 
$$\gamma < 4 \cdot \operatorname{diam} \gamma$$
.

*Proof.* Assume contrary; that is, there is convex surface  $\Sigma \subset \mathbb{R}^3$  and a geodesic  $\gamma \colon [0,4] \to \Sigma$  is parametrized by its length with diam  $\gamma \leqslant 1$ .

Denote by  $\nu_0$ ,  $\nu_2$  and  $\nu_4$  the outer unit normal vectors to  $\Sigma$  at  $\gamma(0)$ ,  $\gamma(2)$  and  $\gamma(4)$  correspondingly.

Note that  $\angle(\nu_0, \nu_2), \angle(\nu_2, \nu_4) \geqslant \frac{2}{3} \cdot \pi$  and  $\angle(\nu_0, \nu_2) > \frac{2}{3} \cdot \pi$ , a contradiction.

# 5. Reduction to a monotonic case

In this section we show that to prove the Main theorem, it is sufficient to consider only the geodesics which go almost in one direction.

**5.1. Proposition.** Assume Main Theorem does not hold; that is, there is a sequence of convex surfaces  $\Sigma_n$  and a sequence of minimizing geodesic  $\gamma_n$  in  $\Sigma_n$  such that

$$\operatorname{TotCur} \gamma_n \to \infty \quad as \quad n \to \infty.$$

Then we can assume in addition that  $\Sigma_n$  is smooth and  $\gamma'_n(t)$  is arbitrary close to a constant vector.

*Proof.* Note that total curvature is lower semicontinuous on the space of curves. Therefore, by Proposition 3.1, we can assume that  $\Sigma_n$  are smooth.

Take a sequence of surfaces  $\Sigma_n$  with a sequence of minimizing geodesics  $\gamma_n$  such that

$$\operatorname{TotCur} \gamma_n \to \infty$$
.

Denote by  $K_n$  the convex body bounded by  $\Sigma_n$ .

Applying rescaling, we can assume that  $\operatorname{diam} \gamma_n = 1$  for all n. By Lemma 4.2 length  $\gamma_n < 4$ . Therefore we can subdivide  $\gamma_n$  into say 100000 arcs such that the legth of each arc is at most  $\frac{1}{100}$  and it lies on the distance  $1 \pm \frac{1}{100}$  from a point  $p \in K_n$ . Choose among them the arc with the maximal total curvature and name it  $\gamma_n$  and translate whole space so the corresponding point p becomes the origin; we still have that  $\operatorname{TotCur} \gamma_n \to \infty$  as  $n \to \infty$ .

Let us apply Liberman's Lemma to  $\gamma_n$  and reference point  $p_n$ . We get that  $\text{TotCur}_p \gamma_n < \pi + \frac{1}{10}$ . Therefore we can divide  $\gamma_n$  into say 100000 arcs again so

that total curvature of each arc in direction of  $p_n$  is at most  $\frac{1}{100}$ . In particular on each arc the angle between  $\gamma(t)$  and  $\gamma'(t)$  is a constant  $\pm \frac{1}{100}$ . Choose among the arcs the one which has maximal total curvature and name it  $\gamma_n$  again; we still have that  $\text{TotCur}\,\gamma_n \to \infty$  as  $n \to \infty$ ; denote by  $\alpha$  the angle between  $\gamma(t)$  and  $\gamma'(t)$  at some point of the arc.

If  $\alpha$  is sufficiently close to  $\pi$  or 0 then  $\gamma_n$  runs almost in the direction of  $\pm \gamma(t)$ ; in this case we finished the proof.

Assume  $\alpha$  is sufficiently far from  $\pi$  and 0. Applying Lemma 4.1 we get a nondegenerate (say isosceles and right-angled) triangle  $\triangle a_1 a_2 a_3$  in  $K_n$  of the size comparable to diam  $\gamma$  and on the distance comparable to diam  $\gamma$  from  $\gamma$ .

Apply the construction to each vertex of the triangle. We pass to an arc of  $\gamma_n$  such that the angle between  $\gamma'(t)$  and  $a_i - \gamma(t)$  is nearly constant for each i. The later imply that  $\gamma'$  is nearly constant.

### 6. Angle estimates

Fix a (x, y, z)-coordinates on the Euclidean space. The lines parallel to the z-axis will be called *vertical*; the lines and planes parallel to (x, y)-plane will be called *horizontal*.

Given a vector  $\boldsymbol{v} \in \mathbb{R}^3$ , we will denote by  $v_x$ ,  $v_y$  and  $v_z$  its components. Set

$$e_x = (1, 0, 0), e_y = (0, 1, 0) \text{ and } e_z = (0, 0, 1).$$

Let  $\Sigma$  be a convex surface and  $\gamma \colon [0,\ell] \to \Sigma$  is a minimizing geodesic with unit-speed parametrization.

Given  $t \in [0, \ell]$ , consider the oriented orthonormal frame  $\lambda(t), \mu(t), \nu(t)$  such that  $\nu(t)$  is the outer normal to  $\Sigma$  at  $\gamma(t)$ , the vector  $\mu(t)$  is horizontal and therefore the vector  $\lambda(t)$  lies in the plane spanned by  $\nu(t)$  and the z-axis.

**6.1. Observation.** According to Proposition 5.1, we can assume that  $\gamma'_z(t) > 0$  for any t and both ends of  $\gamma$  lie on the z-axis.

In particular,  $\nu(t)$  can not be vertical and therefore the frame  $(\lambda, \mu, \nu)$  is uniquely defined for any  $t \in [0, \ell]$ .

After rotating (x, y)-plane if necessary, we can assume that the border of shadow in the directions of x-axis, say  $\omega_x$ , is a smooth curve and  $\gamma$  intersects them transversely.

Let  $t_1 < t_2 < \cdots < t_k$  be the time moments in  $[0, \ell]$  at which  $\gamma$  intersects  $\omega_x$ . Note that  $\mu(t_n) = s_n e_x$  for some  $s_n = \pm 1$ .

Further denote by  $\alpha(t)$  the signed angle between  $\gamma'(t)$  and  $\lambda(t)$  in the tangent plane at  $\gamma(t)$ . Since  $\gamma'_z > 0$ , we can (and will) assume that  $\alpha(t)$  takes values in  $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ . Set

$$\alpha_n = \alpha(t_n).$$

Note that

$$\operatorname{TotCur}_{\boldsymbol{e}_x} \gamma \leqslant 2 \cdot \pi + \operatorname{TotCur}_{\boldsymbol{e}_x} \left( \gamma |_{[t_1, t_k]} \right) =$$

$$= 2 \cdot \pi + \left| \sum s_n \cdot \alpha_n \right|.$$

Consider yet two more angle functions.

- $\diamond$  Let  $\varphi(t)$  be the angle between  $\gamma'(t)$  and z-axis. Set  $\varphi_n = \varphi(t_n)$ .
- $\diamond$  Let  $\psi(t)$  be the signed angle between  $\nu(t)$  and (x,y)-plane. Set  $\psi_n = \psi(t_n)$ . Note that

$$\varphi(t) \geqslant |\psi(t)|$$
 and  $\varphi(t) \geqslant |\alpha(t)|$ 

for any t. In particular

$$\varphi_n \geqslant |\psi_n|$$
 and  $\varphi_n \geqslant |\alpha_n|$ 

for any n.

**Horizontal rotation.** Note that  $\mu(t)$  is horizontal for any t.

Define the rotation  $\rho[a,b]$  of the interval  $[a,b] \subset [0,\ell]$  as the algebraic rotation of  $\mu(t)$  around the origin in (x,y)-plane; say it can be defined by the formula

$$\rho_{[a,b]} = \int_{a}^{b} \langle \mu(t), J(\mu'(t)) \rangle \cdot dt,$$

where  $J : \mathbb{R}^2 \to \mathbb{R}^2$  denotes the rotation by angle  $\frac{\pi}{2}$  around the origin.

$$\rho[t_i, t_{i+1}] = \frac{\pi}{2} \cdot (s_i + s_{i+1}).$$

**6.2.** Claim. Assume that

$$\gamma_z(t_i) \geqslant \frac{1}{2} \cdot (\gamma_z(\ell) + \gamma_z(0))$$
 and  $\left| \sum_{n=i}^{j} s_n \right| = 4.$ 

Then  $\psi(t) > 0$  for any  $t \ge t_i$ .

Note that the claim implies that from  $t_j$ , the geodesic  $\gamma$  lies on a graph z = f(x,y) of a concave function  $f \colon \mathbb{R}^2 \to \mathbb{R}$  and forms a minimizing geodesic in this graph. Indeed fix  $\varepsilon > 0$  such that  $\psi(t) > \varepsilon$  for any  $t \geqslant t_j$ . Consider the set W which lies under all the supporting planes such that its outer normal vector forms angle at most  $\frac{\pi}{2} - \varepsilon$  with the vertical direction. Note that the set W forms a subgraph  $z \leqslant f(x,y)$  of a concave  $(\operatorname{ctg} \varepsilon)$ -Lipschitz function  $f \colon \mathbb{R}^2 \to \mathbb{R}$  and all the points of  $\gamma$  lie the graph z = f(x,y)

*Proof.* Assume contrary, that is  $\varphi(t) \leq 0$  for some  $t \geq t_j$ . Let us draw the half-plane  $\Pi$  through  $\gamma(t)$  bounded by the z-axis. Note that  $\Pi$  intesects the arc  $\gamma|_{[t_i,t_j]}$  at some point say  $\gamma(t')$ . Consider the sub-arc  $\sigma$  of  $\Sigma \cap \Pi$  from  $\gamma(t)$  to z. Since  $\gamma$  is minimizing we have that

length 
$$\gamma|_{[t',t]} \leq \text{length } \sigma$$
.

Straightforward computations lead to a contradiction.

Note that the last claim imply the following.

**6.3. Proposition.** Assume Main Theorem does not hold; that is, there is a sequence of convex surfaces  $\Sigma_n$  and a sequence of minimizing geodesic  $\gamma_n$  in  $\Sigma_n$  such that

$$\operatorname{TotCur} \gamma_n \to \infty \quad as \quad n \to \infty.$$

Then we can make in addition one of the following assumtions:

(i)  $\Sigma_n$  is a graph  $z = f_n(x, y)$  of a smooth convex function  $f_n \colon \mathbb{R}^2 \to \mathbb{R}$  and  $\gamma'_z(t) > 0$  for any  $t \in [0, \ell]$ .

(ii) 
$$\left| \sum_{n=i}^{j} s_n \right| < 10$$
 for any  $i < j$ .

In particular, from now on  $\psi(t) > 0$  for any  $t \in [0, \ell]$ . Note also that by Liberman's lemma  $\varphi(t)$  is a nondecreasing function on  $[0, \ell]$ . The two cases (i) and (ii) will be done separetely. The case (i) is more involved.

**6.4. Claim.** Let  $[a,b] \subset [0,\ell]$  and  $\rho[a,b] \geqslant 3 \cdot \pi$ . Then  $\psi(t) \geqslant \varphi(a)$  for any  $t \geqslant b$ .

**6.5. Claim.** Assume  $\psi(t) \geqslant \varepsilon > 0$  for any  $t \in [a,b]$ . Then  $\alpha(b) - \alpha(a) > \varepsilon \cdot \rho[a,b]$ . In particular, either  $|\alpha(a)| > \frac{1}{2} \cdot \varepsilon \cdot \rho[a,b]$  or  $|\alpha(b)| > \frac{1}{2} \cdot \varepsilon \cdot \rho[a,b]$ .

Note that above two claims imply the following.

**6.6. Proposition.** Assume  $\gamma$  as in Proposition 6.3 and for some i < j we have

$$\left| \sum_{n=i}^{j} s_i \right| = 5$$

Then  $\varphi_j > 2 \cdot \varphi_i$ .

# 7. The sum estimate

There is no geometry in this section. Here we give an estimate for a sum of finite sequence of real numbers of a very specific form.

Assume a finite sign-sequence  $s = (s_1, \ldots, s_k)$  is given; that is  $s_i = \pm 1$  for i. We say that a pair of indexes i < j forms an s-pair if

$$\sum_{n=i}^{j} s_n = 0 \qquad \text{and} \qquad \sum_{n=i}^{j'} s_n > 0$$

if i < j' < j.

Note that for any index i appears in at most one s-pair and for any s-pair (i, j) we have

- $\diamond$   $s_i = 1$ ; that is, *i*-th braket has to be openning.
- $\diamond$   $s_j = -1$ ; that is, j-th braket has to be closing.

**Bracket interpretation.** If you exchange "+1" and "-1" in s by "(" and ")" correspondingly then (i, j) is an s-pair if and only if the i-th bracket forms a pair with j-bracket.

We say that q is the depth of an s-pair (i,j) (briefly  $q = \operatorname{depth}_{s}(i,j)$ ) if q is the maximal number such that theis q-long nested sequence of s-pairs starting with (i,j); that is a sequence of s-pairs  $(i,j) = (i_1,j_1), (i_2,j_2), \ldots, (i_q,j_q)$  such that

$$i = i_1 < \dots < i_q < j_q < \dots < j_1 = j.$$

## 7.1. Proposition. Assume that

- $\diamond s_1, \ldots, s_k$  is a sign sequence,
- $\diamond 0 \leqslant K_1 \leqslant K_2 \leqslant \ldots \leqslant K_k.$
- $\diamond$  a sequence  $\alpha_1, \ldots, \alpha_k$  is such that for **s**-pair (i, j), we have

$$|\alpha_i - \alpha_j| \leq \operatorname{depth}_{\mathbf{s}}(i, j) \cdot (K_j - K_i),$$

 $0 \le \varphi_1 \le \ldots \le \varphi_k \text{ such that } \varphi_i \ge |\alpha_i| \text{ for any } i \text{ and } \varphi_j > 2 \cdot \varphi_i \text{ for any } j > i \text{ such that } |\sum_{n=i}^j s_n| = 5.$ 

Then

$$|\sum s_n \cdot \alpha_n| \leqslant 20 \cdot (K_k + \varphi_k).$$

*Proof.* Note that for arbitrary the s-pairs (i, j) and (i', j') we have three possibllities:

- $\diamond [i,j] \subset [i',j']$  and in this case depth<sub>s</sub> $(i,j) < \text{depth}_s(i',j')$ ;
- $\diamond [i,j] \supset [i',j']$  and in this case depth<sub>s</sub> $(i,j) > \text{depth}_s(i',j')$ ;
- $\diamond [i,j] \cap [i',j'] = \varnothing.$

In partcular, if depth<sub>s</sub> $(i,j) = \text{depth}_s(i',j')$  then the intervals [i,j] and [i',j'] do not overlap.

Therefore if

$$S_q = \sum_{\text{depth}_s(i,j)=q} (\alpha_i - \alpha_j)$$

is the sum for all s-pairs with depth q then

$$|S_q| \leqslant q \cdot K_k$$
.

Since  $s_i = 1$  and  $s_j = -1$  for any **s**-pair (i, j), we have

$$\alpha_i - \alpha_j = s_i \cdot \alpha_i + s_j \cdot \alpha_j.$$

That is, one can partition  $\{1, \ldots, k\}$  into two sets, say H and G such that

$$S_1 + S_2 + S_3 + S_4 + S_5 = \sum_{i \in H} s_i \cdot \alpha_i$$

An index i belongs to G if it does not form an s-pair or its s-pair has depth at least 6. Let us subdivide G into 5 groups, say  $G_1, \ldots, G_5$  so i and j go into the same group if

$$\sum_{n=i}^{j} s_n \equiv 0 \pmod{5}.$$

Note that

$$\left| \sum_{n \in G_m} s_n \cdot \alpha_n \right| \leqslant \sum_{n \in G_m} \varphi_n \leqslant$$

$$\leqslant 2 \cdot \varphi_k;$$

the last inequality follows since  $(\varphi_i)$  is an increasing sequence and  $\varphi_j > 2 \cdot \varphi_i$  if  $i, j \in G_m$  and i < j.

Summarizing

$$\left| \sum_{n} s_{n} \cdot \alpha_{n} \right| \leqslant \sum_{i=1}^{5} \left| S_{i} \right| + \sum_{i=1}^{5} \left| \sum_{n \in G_{i}} s_{n} \cdot \alpha_{n} \right| \leqslant$$

$$\leqslant 15 \cdot K_{k} + 10 \cdot \varphi_{k}.$$

Hence the result follows.
